

Learn About Genetic Testing

What is a gene?

Genes are pieces of your DNA. Your DNA is found inside every cell in your body. Your genes tell your body how to work.

Each gene has a role in your body. Some genes affect traits like your hair colour, eye colour and height. Other genes affect your risk for certain diseases, like cancer.

You get your genes from your parents. Half of your genes are from your mom. The other half of your genes are from your dad.

What is hereditary (inherited) cancer?

Hereditary (inherited) cancer means a gene mutation is passed from one generation to another. A gene mutation is a change in a gene that stops the gene from working as it should. A gene mutation can raise your risk for cancer.

Families with hereditary cancers can have:

- cancer at a young age
- more than one cancer in the same person
- rare types of cancers or tumours
- many family members with cancer

Note: Cancer can still be hereditary even if there is no family history.

A small number of people get cancer because of an inherited gene mutation. Approximately **10 people out of 100 (10%)** get their cancer because of a gene mutation. Most people who have cancer get their cancer by chance. **90 people out of 100 (90%)** get their cancer by chance.

■ **90 people out of 100 (90%)** get their cancer by chance

■ **10 people out of 100 (10%)** get their cancer because of a gene mutation

For some cancers, more than 10% of people get their cancer because of a gene mutation

What is genetic testing?

Genetic testing is a blood or saliva (spit) test that looks at your genes. Genetic testing looks for mutations in your genes.

Some genetic tests look for mutations in many genes at the same time. This test is called a panel test. Many genetic tests are panel tests.

Your cancer risk depends on many factors. Some important factors linked to your cancer risk are gene mutations and family history of cancer. Your cancer risk also changes depending on the gene mutation found.

Your doctor or genetic counsellor will discuss if genetic testing is right for you. If you are offered genetic testing by your doctor or genetic counsellor, it should not cost you money. In Canada, genetic testing is usually covered by government funded health insurance.

To learn more about genetic testing, watch the videos on our Princess Margaret Familial Cancer Clinic site: genetics.theprincessmargaret.ca.

How can genetic testing help me?

Genetic testing can help you in many ways. Genetic testing can help you:

- know why you got cancer
- decide your cancer care
- know your risk of getting other cancers
- make choices about cancer screening and risk reduction. Risk reduction means lowering your risk of cancer.

How can genetic testing help my family?

If you have a gene mutation, your family members may also have this gene mutation. Your gene mutation was likely passed down to you from one of your parents. This mutation can also be passed on to your children. Your brothers, sisters, aunts, uncles, and cousins may also have this gene mutation.

If you have a gene mutation, genetic testing will be offered to your family members. This testing helps figure out whether your family members have a higher risk for cancer. If your family members have the gene mutation, their health care team may suggest changes to their health care. Health care changes may include cancer screening and risk reduction.

What are the possible results of my genetic testing?

There are 3 possible results of your genetic test. The 3 results are outlined below.

1. Mutation detected

This result means you have a mutation in one of the genes tested. Your lab report may say that a “pathogenic variant” has been detected. Mutations can also be called “pathogenic variants”. This result means:

- You have a higher risk for some cancer types
- There may be changes to your cancer screening, treatment, and/or risk reduction plans
- Your family members will likely be offered genetic testing.

2. No mutation detected

This test result means a gene mutation was not found. This result means:

- There is no change in your cancer screening, treatment, and/or risk reduction plans
- Cancer risk is based on personal risk factors and family history of cancer
- Your family members will likely not be offered genetic testing.

3. Variant of uncertain significance detected

This result means that a change was found in one of the genes tested but the genetics experts do not know if it is linked to cancer risk. A variant of uncertain significance (VUS) is the medical term used to describe this result. You may notice this medical term used on your genetic testing results. This result means:

- There is no change in your cancer screening, treatment, and/or risk reduction plan
- Cancer risk is based on personal risk factors and family history of cancer
- Your family members may be offered genetic testing if they also have cancer. This testing helps find out the meaning of the VUS found.

What if I have more questions about genetic tests?

Talk to your doctor if you have any questions about genetic testing. Your doctor can refer you to a genetic counsellor if you have more questions. A list of Canadian genetics clinics can be found on the Canadian Association of Genetic Counsellors website (www.cagc-accg.ca).
